

Transcript-Derived Ransomware Knowledge Dataset – Summary Report

This document summarises the dataset constructed for the proposed Knowledge Agent component in the SABRE ransomware detection framework. The dataset was created by collecting transcripts from cybersecurity practitioner videos (e.g., DFIR incident walkthroughs, conference talks, and threat intelligence briefings) and extracting structured ransomware knowledge signals.

Dataset Stage	Count / Description
Curated YouTube Channels	50 security-focused channels
Transcripts Collected	440 videos with available transcripts
Minimum Video Length	≥ 5 minutes (quality constraint)
Selected Videos After Rubric Filtering	307 videos
Transcript Files	.txt paired with .meta.json for reproducibility

Ransomware Family	Mentions in Dataset
Play	149
Qilin	37
Akira	10
Royal	9
LockBit	9
Hive	7

ATT&CK-like Tactic	Mentions
Initial Access	2105
Execution	791
Persistence	772
Impact	651
Privilege Escalation	237
Exfiltration	209

Platform	Mentions
Windows	1072
Linux	444
ESXi	109

The dataset includes structured features extracted from transcripts such as ransomware family mentions, tool usage, ATT&CK-like tactics, and platform indicators. These signals are converted into a machine-learning feature matrix (Knowledge_Agent_Features_307.csv), which forms the

input dataset for training the Knowledge Agent component of the SABRE architecture. Each row corresponds to a single video transcript and includes traceability fields (YouTube URL and transcript path) to ensure full reproducibility of the dataset.
